General practitioners have a pivotal role in ensuring patients receive the best possible care and a holistic approach to achieving the optimum quality of life.

Every patient with rheumatic disease will require help from a number of different healthcare professionals throughout their life but it is the unique lifelong relationship with their primary care physician which is most important.

Rheumatoid arthritis is the commonest inflammatory polyarthropathy in the UK with the average general practitioner having 20 patients in a population of 2000. Musculoskeletal complaints accounts for up to 25% all consultations and patients with rheumatoid arthritis consult regularly.

The important aspects of a good doctor patient relationship were explored by holding a forum meeting of rheumatoid arthritis patients and a similar meeting with a group of doctors. Interestingly, both groups agree on the main features of a good relationship. According to the patients, the good doctor with whom they were able to form an excellent relationship had a patient centred approach characterised by active listening, allowing sufficient time in the consultation, showing of sympathy and providing a whole person approach.

General practitioners recognised the importance of good communication within the consultation to identify the patient's fears, concerns and expectations, and their priorities were also active listening, an holistic approach and giving the patient sufficient time to identify their agenda and formulate a joint management plan.

The forum groups also considered how this relationship could be improved. Patients felt that their general practitioner needed to have more awareness of rheumatoid arthritis and to be more willing to refer at an earlier stage which has been confirmed by the King's Fund Report commissioned by the Rheumatology Futures Group and published in January this year.

The areas a good patient centred consultation need to address were considered including the exploration of the patient's main concerns which can be often non-specific symptoms such as fatigue, the limitation of the patient's functional ability to carry out certain activities, and work-related issues such as loss of self-esteem and financial problems. In comparison, doctors have tended to focus on the objective assessment of joint activity and loss of functional ability, for example, by measuring the number of swollen tender joints and using the HAQ score. The holistic approach is vital in rheumatoid arthritis not just to identify the patient's real concerns but to address other important areas of co-morbidities such as depression, cardiovascular disease and osteoporosis.

The way in which management choices are discussed and agreed include an explanation of the risks of each option presented in an easily understood way using appropriate language. The patients' desire to have immediate benefit from treatment has to be balanced against the long-term benefits which most doctors aim for. The use of corticosteroids, joint injections and increased analgesia play a crucial role in providing short-term relief of symptoms. The risks benefits ratio for all treatments need to be discussed honestly with clear easily assimilable information which encompasses the patient's concerns regarding treatment.

Trust and honesty is vital in the doctor patient relationship and will improve compliance and adherence to joint management plan. Trust is fostered by a patient centred approach and patient trust in the doctor has been shown to have the greatest effect on DMARD decision making. The other benefits of a long-term doctor patient relationship are examined and include knowledge of each other, a mutual friendship bond and loyalty to an individual doctor.

The influence of official guidance on present management is discussed including the current NICE guidelines for osteoarthritis and rheumatoid arthritis, the role of the RCGP and the final report of Lord Darzi's Next Stage Review which supports high quality care for all at the centre of the new NHS with empowerment of patient playing a key role. Inflammatory care pathways are being commissioned to provide a minimum standard of care for patients with rheumatic diseases and personalised care plans will help to maintain patients' autonomy.

Empowerment means supporting patients to take responsibility for their own health, raising the awareness of patients to the key features of musculoskeletal disease, explaining the advantages of early intervention or advising them to avoid any delay in seeking treatment if they experience joint problems. There is a key role for the arthritis charities in improving patients' education in these areas.

A patient with rheumatic disease requires regular support over the years and the impact of a good long-term relationship with their doctor is immeasurable in enabling the patient to achieve the optimum quality of life. General practitioners have a pivotal role in ensuring patients receive the best possible care and a holistic approach to achieving the optimum quality of life.

Abstract: The establishment of a good long-term relationship between the doctor and the patient with rheumatic disease is essential in order to optimise treatment and to enable the patient retain control over their disease.
